## 1 Attack on PSS

1.  $B \rightarrow I(A) : N_B$
2.  $I \rightarrow A : N_I$
3.  $A \rightarrow I : \{K_{AI}, A, N_A, N_I\}_{pub(I)}$
4.  $I(A) \rightarrow B : \{K_{AI}, A, N_A, N_B\}_{pub(B)}$
5.  $B \rightarrow I(A) : \{|\{N_B, N_A - 1\}_{pub(A)}|\}_{K_{AI}}$
6.  $I(A) \rightarrow B : \{|N_B - 1|\}_{K_{AI}}$
7.  $I \rightarrow A : \{|\{N_B, N_A - 1\}_{pub(A)}|\}_{K_{AI}}$
8.  $A \rightarrow I : \{N_B - 1\}$

## 2 Attack Description

### 2.1 Attack Flow

- **Message 1:**  $B$  initiates the protocol, believing they are establishing a session with  $A$ .  $B$  sends their fresh nonce  $N_B$  to what they think is  $A$ , but the intruder  $I$  intercepts this message while impersonating  $A$ . The intruder stores  $N_B$  for later use in the attack.
- **Message 2:** The intruder  $I$  initiates a separate, parallel session with  $A$ .  $I$  sends their own nonce  $N_I$  to  $A$ , who believes they are receiving a legitimate protocol initiation from  $I$ .
- **Message 3:**  $A$  responds by generating a session key  $K_{AI}$  (intended for secure communication with  $I$ ) and their own nonce  $N_A$ .  $A$  encrypts the tuple  $\{K_{AI}, A, N_A, N_I\}$  using  $I$ 's public key  $pub(I)$  and sends it to  $I$ . Since  $I$  possesses the corresponding private key, they can decrypt this message and obtain  $K_{AI}$  and  $N_A$ .
- **Message 4:** This is the critical step of the attack. The intruder  $I$  impersonates  $A$  to  $B$  by constructing a fraudulent message.  $I$  reuses the session key  $K_{AI}$  that  $A$  generated for them, but substitutes the nonce  $N_I$  with  $B$ 's original nonce  $N_B$ . The message  $\{K_{AI}, A, N_A, N_B\}_{pub(B)}$  is encrypted with  $B$ 's public key, making it appear as a legitimate response from  $A$  to  $B$ 's initial request.  $B$  decrypts this message and believes that  $A$  has established a shared session key with them.

- **Message 5:**  $B$  continues the protocol by computing  $N_A - 1$  and encrypting  $\{N_B, N_A - 1\}$  with  $A$ 's public key, then encrypting the result again with what  $B$  believes is the shared session key (actually  $K_{AI}$ ).  $B$  sends this double-encrypted message to what they think is  $A$ , but  $I$  intercepts it.
- **Message 6:** The intruder  $I$ , still impersonating  $A$  to  $B$ , completes the protocol with  $B$  by computing  $N_B - 1$  and sending it encrypted under  $K_{AI}$ .  $B$  can verify this response and believes the protocol has completed successfully with  $A$ .
- **Message 7:** Meanwhile,  $I$  forwards the double-encrypted message from Message 5 to the real  $A$ . Since the inner encryption uses  $A$ 's public key and the outer encryption uses  $K_{AI}$  (which  $A$  established with  $I$ ),  $A$  can decrypt it successfully.
- **Message 8:**  $A$  completes their session with  $I$  by computing  $N_B - 1$  and sending it encrypted under  $K_{AI}$ . Note that  $A$  believes they are completing the protocol with  $I$ , using nonce  $N_B$  that  $I$  had sent in Message 2.

## 2.2 Attack Results

At the conclusion of this attack, both  $A$  and  $B$  believe they have successfully established a secure session with each other using the session key  $K_{AI}$ . However, this session key was actually generated by  $A$  for communication with the intruder  $I$ . Since  $I$  possesses this key, they can decrypt and read all subsequent messages exchanged between  $A$  and  $B$ .

More precisely:

- $A$  believes they completed the protocol with  $I$  and that  $K_{AI}$  is shared only with  $I$
- $B$  believes they completed the protocol with  $A$  and that  $K_{AI}$  (which  $B$  thinks is  $K_{AB}$ ) is shared only with  $A$
- In reality,  $I$  knows  $K_{AI}$  and can act as a man-in-the-middle, decrypting, reading, and potentially modifying all messages between  $A$  and  $B$

This is a classic man-in-the-middle attack that exploits the protocol's failure to adequately bind the session key to both participants' identities in a way that prevents such substitution attacks.
